1 **ABSTRACT**

2 Approximately one quarter of all U.S. air-passenger trips (involving US airlines only) are to and  
3 from foreign destinations, accounting for around 4.5 percent of total US person miles in 2019.  
4 Travel demand modeling and US travel surveys often overlook this overseas travel. Therefore, this  
5 study assesses travel demand, patterns, and costs (in time and money) between major US and  
6 foreign airports worldwide, as well as ground trips to Mexico and Canada, using 2019 DB1B flight  
7 ticket data, the 2016 -17 National Household Travel Survey (NHTS), and border crossing data. A  
8 model of trip distribution, from 334 US airports to 1,028 foreign airports shows how trip flows fall  
9 about 41% with every 7-hour increase in flight start to end time. Destinations hosting tourist  
10 attractions (like London, Barcelona, Milan, Paris, Dubai, etc.) are also a practically significant  
11 variable in the model, increasing flows by 48%. Flight fares (for one-way itineraries) increase by  
12 \$0.078 per mile for coach class and \$0.163 per mile for business class and higher, according to  
13 feasible generalized least-squares models. These fares are higher for English-speaking destinations  
14 as compared to other destinations (not English-speaking), as well as for trips from April to June as  
15 compared to January to March with similar distances, flight classes, etc. Understanding  
16 international travel is important for local and global economics, the evolution of transportation  
17 technology and social networks, and the future of global climate and air quality.

19

## 1 INTRODUCTION

2 The fiscal significance of international tourism in the United States cannot be underestimated. In  
3 2019, the U.S. tourism supported 9.5 million employment and contributed to 2.9% of GDP, for a  
4 total economic impact of \$1.9 trillion. Foreign tourists spend more money in the U.S. than they do  
5 in any other country (14.5 percent of all foreign tourists' money) (1). On average, an American  
6 spent \$1,487 per person and \$2,429 per travel party on an international trip outside the US in 2019  
7 (2). According to a more recent ITA release in 2021, Americans spent \$73.9 billion dollars (51%  
8 more than 2020) on international trips, resulting in trade excess of \$6.2 billion (\$2.1 billion was  
9 added just in December 2021) (3). According to the US Bureau of Transportation Statistics (BTS),  
10 person-miles travelled (PMT) in 2019 were 7.7 trillion, of which 4.5% were international person-  
11 miles involving US air carriers (4). BTS air passenger data suggest that the “average” American  
12 makes 0.37 international trips (inbound and outbound) per year by air, boat, road, and train. This  
13 implies an international departure by air every 5.43 years (2, 4). The major purposes of these trips  
14 (84% of the total) were leisure or visiting friends and relatives (2). Air travel accounts for 60% of  
15 the international travel from U.S., land travel accounts for more than 39% (to Mexico and Canada)  
16 and travel through water (to Canada) is less than 1% (4, 5). In addition to being a key source of  
17 household expenditure and national GDP contributor, air travel is a significant source of travel-  
18 based emissions and passenger-miles traveled. Thus, analyzing overseas travels and  
19 their destinations holds significant importance in the advancement of future tourism policies,  
20 including the regulation of prices, provision of adequate infrastructure and control of  
21 environmental quality (6).

22 Travel demand modeling studies and U.S. travel surveys regularly miss international travel.  
23 Most studies focus on domestic trips, and very few include questions on long-distance trips (from  
24 the past month or year, rather than simply catching the few that happen on the survey day).  
25 However, international trips are a notable source of travel cost and emissions, with 8% of global  
26 greenhouse gas (GHG) emissions produced via tourism, and 40% of those emissions coming via  
27 aviation (7). Llorca et al. (8) developed a model for generation, distribution, and mode choice in  
28 person trips over 40 km (25 miles, one-way) – but only from Ontario province, in Canada. They  
29 observed that land use attributes and trip purpose (or destination activities) are important for  
30 destination choice probabilities. For international trip generation, they estimated only the total  
31 number of trips (not destination or mode or timing), due to the lack of data.

32 Transport planning heavily relies on forecasts of travelers' trip decisions, including  
33 international travel. Tourism flows and international trade volumes do show up in the literature,  
34 especially for specific market pairs. For example, Qu and Lam (9) used ordinary least squares  
35 models to estimate travel demand for mainland Chinese tourists to Hong Kong. They identified  
36 income and visa requirements as key predictors. Keum (10) used a gravity model and Linder  
37 economic hypothesis to predict trade patterns and tourism flows across Korea. The study  
38 confirmed the robustness of the gravity model in estimating international flows. Wu et al. (11)  
39 explored tourism flows between Chinese regions and offered suggestions for tourism  
40 improvements. Most of studies focus only on international flows between specific places (e.g., like  
41 US to Canada (12)) or all in-coming flows (e.g., Zhang et al. (13)). However, international business  
42 trips are regularly overlooked. Furuichi and Koppelman (14) used a nested logit model to predict  
43 the departure and destination airports of air travelers. They used a survey of international air  
44 travelers from Japan and indicated that a joint departure airport and destination choice better  
45 predicts leisure and business international travels than multinomial logit models.

1 Air is a major mode for trips over 500 miles, and international travel. Americans made 100  
2 million international trips to other nations in 2019 (including one-way and round trips from US by  
3 all modes). BTS (5) reported that US airlines handled 115 million air passengers in the same year  
4 - including both Americans and non-American passengers. Airfare and duration are expected to  
5 be important indicators of international travel mode and destination choices. Flight price fluctuates  
6 depending on purchase time, number of stops, flight date, and seat class. Recent studies have used  
7 machine learning algorithms to predict flight fare using different datasets (e.g., 15). Ratnakanth  
8 (16) analyzed different methods presented in the literature for flight price prediction and indicated  
9 that random forest and gradient boosting techniques outperform other machine learning  
10 approaches for flight fare prediction. The study stated airline company, travel time, number of  
11 stops, and destination as effective factors in flight price. Flight fare prediction studies are mostly  
12 used for defining prices in the future for various airlines. In this study, flight fare and duration are  
13 inputs of the trip distribution model and its application. The prior literature primarily focuses on  
14 either tourist destinations or airfare forecasting, resulting in a gap in the all-encompassing  
15 examination of how individuals make decisions regarding international travel and the subsequent  
16 impact on airfares to their selected locations. The current study aims to address the disparity by  
17 undertaking an ambitious effort to elucidate the intricate aspects of international travel behavior.  
18 Through the implementation of an integrated approach, this study combines choice behavior  
19 models that consider demographic factors with destination selection behavior based on multiple  
20 trip attributes. Additionally, this research examines the relationship between fluctuations in flight  
21 prices and destination, time of year, and ticket type.

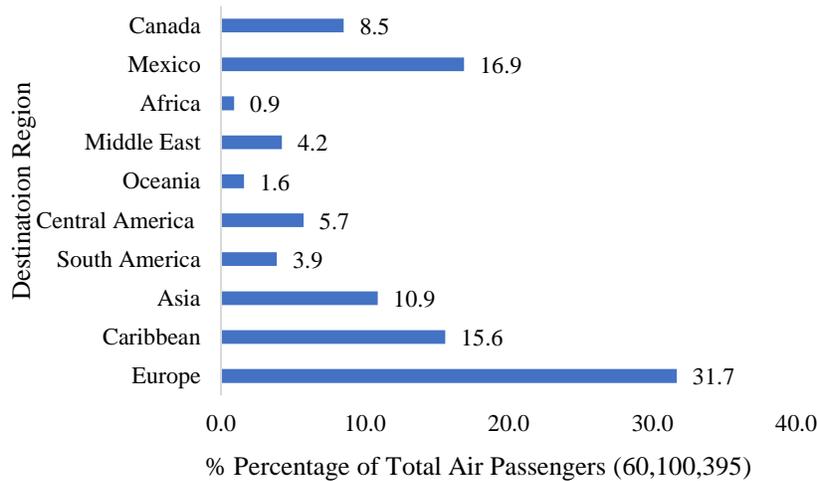

22 The primary objective of this research is to augment the understanding of the global travel  
23 patterns of individuals, with a specific focus on air transportation that originates from the United  
24 States. The goal is to utilize travel demand models to forecast airfare rates, travel time, and the  
25 distribution of trips among major airports in the United States and worldwide. The research relies  
26 on a 10% sample of the 2019 DB1B dataset, which comprises a vast amount of data, encompassing  
27 2.6 million itineraries for roughly 3.9 million travelers. This data is composed of data pertaining  
28 to the sale of airline tickets for passengers, which has been gathered by BTS. The study employs  
29 Feasible Generalized Least Square (FGLS) models as the methodology to estimate airfares for  
30 individual paid itineraries and passengers. Additionally, the FGLS models are utilized to examine  
31 the variance in fares for international round trips originating from the US and one-way journeys  
32 with US origins. A trip frequency model estimated in Fakhrmoosavi et al. (18) was first used to  
33 estimate the number of long-distance trips among Americans. Then, a binomial logistic regression  
34 model is utilized to ascertain the inclinations of Americans towards overseas trips in comparison  
35 to domestic long-distance excursions. Ultimately, a gravity model is utilized to approximate the  
36 dispersion of journeys originating from diverse locations within the United States to global  
37 destinations. The current study expands upon previous studies by presenting demand models for  
38 international trips to and from the US. Most prior studies either focus on domestic travel or a  
39 limited origin-destination sets. In addition, this study uses an FGLS model to predict airfares,  
40 considers heteroskedasticity and autocorrelations. Finally, this study uses multiple data sources,  
41 including the DB1B flight ticket data, 2016-17 NHTS, and multiple other tourism data sources to  
42 estimate the international trip models considering land trips in addition to air travel.

43 The remainder of this paper is organized as follows. The subsequent section provides a  
44 summary of the datasets employed in this investigation for the purpose of approximating models  
45 pertaining to international trip distribution and flight fare explicated. The third section talks  
46 about the estimated models and is subsequently succeeded by the principal findings derived from

1 models. The final segment provides a summary of the study's conclusions, limitations, and  
2 potential future applications.

3  
4 **DATASETS USED**

5 Using international travel datasets, this research examines the overseas destination preferences of  
6 Americans and models the international travel demand to better prepare for future transportation.  
7 This study uses 2019 DB1B flight ticket data, the 2016-17 NHTS as well as publicly available  
8 international travel data collected by the National Travel and Tourist Agency (NTTO), Survey of  
9 International Air Travelers (SIAT), and Travel and Tourism Satellite Account (TTSA). According  
10 to past annual passenger miles recorded by NTTO, international travel accounted for 40% of all  
11 revenue passenger miles travelled by US airlines in 2019 wherein US Flagged carriers handled  
12 47% of total international air passenger to and from the United States (2, 5). The SIAT survey on  
13 US residents visiting overseas countries revealed that European (19.1%) and Caribbean countries  
14 (9.4%) accounted for a large proportion of overseas destinations from US, after Canada and  
15 Mexico (54.9%) (18). Figure 1 shows Americans' rate of travel to different overseas regions in  
16 2019 by air.

17  
18 **Figure 1 Americans' outbound travel by air in 2019 (17)**

19  
20 The main data source in this study is the DB1B ticket data collected by the BTS Office of  
21 Airline Information. This data is a 10% random sample of US airline passenger ticket itineraries  
22 reported by the US flag carriers only. It includes trip origin and destination data, yearly and  
23 quarterly indicators, number of passengers, number of legs, and distance and fare information for  
24 each itinerary. The dataset producers began publishing records in 1993, providing 28 years of  
25 available data. This study uses a 10% sample of the 2019 data (before the COVID-19 pandemic),  
26 which contains 2.6 million itineraries for 3.9 million passengers.

27 TABLE 1 and

28

1 TABLE 2 summarize one-way itineraries to and from the US in the 2019 DB1B data. It  
 2 includes flight fare and distance flown per itinerary, fare per distance flown, party size (i.e., the  
 3 number of individuals per flight ticket), and average number of legs (i.e., segments) per trip.

4 Additionally, the 2016-17 NHTS dataset is used to model Americans' international trip-  
 5 making choices versus a domestic long-distance trip. The trip frequency model for long-distance  
 6 trips (over 75 miles one-way) is estimated using this NHTS dataset leveraged in the study done by  
 7 Fakhrmoosavi (17). With this model, travelers' decisions to make a long-distance international trip  
 8 will be modeled using the 2016-17 NHTS dataset. The 2016-17 NHTS data includes 923,572 trip  
 9 records, which sum to 371 billion trips using NHTS expansion factors. In this dataset, 134.46  
 10 million expanded trips are reported as international trips, which account for only 1 percent of the  
 11 total long-distance trips (~7 billion weighted). The population of 2019 destination nations, as well  
 12 as information about the languages spoken in the destination countries, were collected from the  
 13 United Nations website (19). If English is one of the major languages spoken, this study assumes  
 14 the nation is significantly English-speaking. Additionally, the major tourist attractions in 2019  
 15 were obtained from the 2019 edition of Euromonitor International's city tourist arrivals (20)  
 16 research report that covers over 400 cities worldwide. In the report, a tourist is defined as an  
 17 international tourist who visits another country for at least 24 hours and resides in paid or unpaid,  
 18 group or private lodging for a period not exceeding 12 months.

2

3

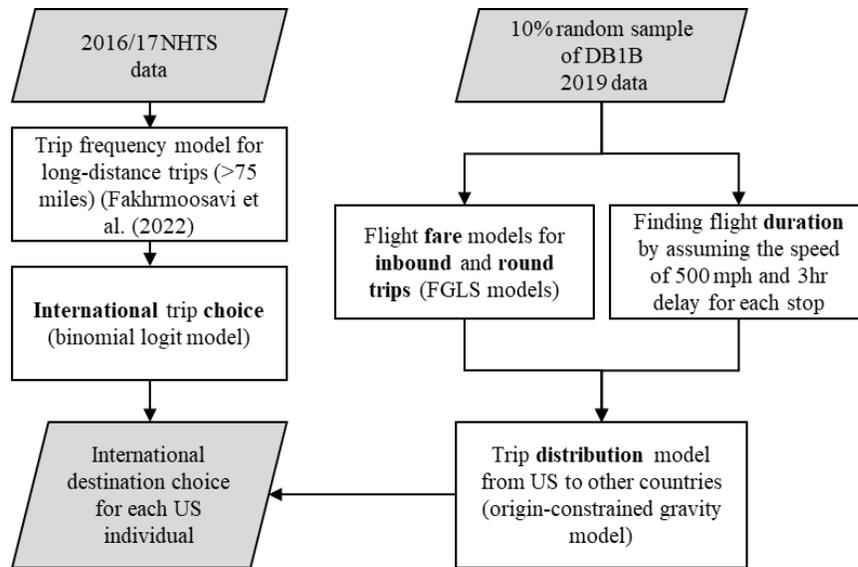

**METHODOLOGY**

4 The main goal of this study is to improve the knowledge of the international travel behaviors of  
5 individuals, with a particular emphasis on air travel originating from the United States. The study  
6 uses the 2016-17 NHTS data to predict the likelihood of Americans' making an international trip.  
7 The decision of whether a traveler chooses to make a long-distance international trip as opposed  
8 to a domestic long-distance trip exceeding 75 miles is evaluated through the application of a  
9 binomial logit model. The modeling framework for international trip distribution by Americans is  
10 depicted in Figure 2. The trip frequency model for long-distance trips (over 75 miles one-way) is  
11 first estimated using the NHTS dataset and a model presented in Fakhmoosavi et al. (17). The  
12 study estimated long-distance trips per day at the individual level using a zero-inflated negative  
13 binomial (ZINB) model and the 2016-17 NHTS data. The zero-inflated negative binomial model  
14 comprises two components: firstly, a logit model that determines the likelihood of an individual  
15 undertaking a long-distance trip, and secondly, a negative binomial count model that estimates the  
16 count of trips made. The population weights are utilized in order to improve the accuracy of  
17 parameter estimates in reflecting the demographics at the household and individual levels in the  
18 United States. Then, for each trip inside this trip frequency, the binomial logit model stated earlier  
19 is used to estimate the decision between domestic and international long-distance trip.  
20

21 Table 3 presents the parameters that are statistically significant in the model for long-  
22 distance trip frequency. The table further shows the practical significance of these variables,  
23 i.e., the effects of a one standard deviation increase in each covariate on trip frequency. The  
24 parameter estimates of the count model indicate that there is an increase of nearly 51% in long-

1 distance trip rates when there is a 1 standard deviation rise in the natural logarithm of household  
 2 annual income, which is measured in US dollars. The skewing of the population-weighted sample  
 3 by one standard deviation towards males resulted in a 21.6% increase in the mean frequency of  
 4 long-distance trips. An addition of one standard deviation in the number of vehicles owned by  
 5 households resulted in a 66% rise in the frequency of long-distance trips. The distribution of trips  
 6 from US origin airports to international airports in other countries is done through the use of an  
 7 origin-constrained gravity model and DB1B data. This model employs flight duration and fare, an  
 8 English language country indicator, a tourism attraction country indicator, and the population of  
 9 the country as its inputs. The DB1B data does not include information regarding the duration of  
 10 flights. Therefore, the estimation presented here is based on the average speed and delay for each  
 11 stop. Furthermore, FGLS models are utilized to estimate flight fares and their fluctuations for  
 12 outbound and roundtrips originating from the United States, with the intention of incorporating  
 13 these findings into model implementations.

## 1 RESULTS

2 This study presents three distinct sets of findings. Firstly, the FGLS models are introduced to  
 3 predict airfares for individual paid itineraries. Subsequently, the outcomes of the binary choice  
 4 model used to determine the likelihood of an American embarking on international travel have  
 5 been explained. The impact of the destination and trip attributes on destination selection is then  
 6 discussed with the aid of estimated gravity model.

### 8 *Flight Fare and Duration Models*

#### 9 *International Round Trips - US Origin*

10 FGLS models for 2019 round-trip itineraries (TABLE 4) indicate that the flight fare decreases  
 11 whenever 1) an intermediate stop is included in an otherwise uninterrupted trip, and 2) the number  
 12 of passengers on the itinerary increases. The cost of air travel for coach class passengers rises by  
 13 \$0.058 per mile, whereas for business class or higher passengers, the rise is \$0.281 per mile. The  
 14 cost of air travel to a country with a higher population density is comparatively lower than that of  
 15 a country with a lower population density. This can be attributed to the increased number of flights  
 16 to densely populated countries, leading to heightened competition among airlines, and consequent  
 17 reduction in airfare. It is noteworthy to observe that the cost of a return journey to an English-  
 18 speaking nation is comparatively lower than that of a trip to a non-English speaking destination.  
 19 The cost of travel during the months of October to December is comparatively higher than that of  
 20 other months throughout the year. Shifting all samples towards business or higher class and  
 21 towards United Airlines increases the flight fare by 150% and 7.5%, respectively. TABLE 5  
 22 presents the model estimates when the log of linear model residuals is regressed on all dependent  
 23 variables. The table indicates that the coefficients show a significant deviation from zero, thereby  
 24 implying the existence of heteroscedasticity. A positive coefficient indicates a direct relationship  
 25 between the independent variable and the variance of the errors, such that a rise in the independent  
 26 variable is associated with a rise in the variance of the errors. A coefficient with a negative value  
 27 indicates an inverse relationship. The results show that the flight prices of itineraries with more  
 28 than 1 stop, travel to non-English speaking destinations, and trips with more than one party size  
 29 vary significantly in price compared to others.

1  
2 *International One-way Trips - to and from US*  
3 The FGLS model results for air fares of international one-way trips to and from US is shown in  
4 TABLE 6, and the variance model estimates are shown in TABLE 7. The estimated model  
5 coefficients reveal that a flight price costs \$0.078 per mile flown for coach class and \$0.163 per  
6 mile flown for business class or higher. The flight fare decreases as the number of passengers rises,  
7 and the numbers of stops on the itinerary increases. A trip made from April to June shows high  
8 variation as compared to other days of the year. Shifting the sample towards business or higher  
9 class increases the flight fare by 125%, while the same shift towards Southwest Airlines decreases  
10 the cost by 58.5%. There is a similar trend found in one-way flight fares as we found in round  
11 trips, which is that the cost of air travel to a country with a higher population density is  
12 comparatively lower than that of a country with a lower population density. Additionally, the cost  
13 of a return journey to an English-speaking nation is comparatively lower than that of a trip to a  
14 non-English speaking destination. Variance model estimates are shown in Table 7. The estimates  
15 indicate that the flight prices of the itineraries with more than 1 stop, travel to non-English speaking  
16 destinations, and trips with more than one party size vary significantly in price compared to others.

2 ***International Trip Choice***

3 A binomial logit model has been employed to determine the preference of American individuals  
4 for international travel as opposed to domestic travel. The study assesses the likelihood of making  
5 an international trip by considering demographic factors, temporal factors, and the purpose of the  
6 trip. The specifications of the logistic regression model for estimating international trip choice for  
7 Americans are shown in TABLE 8. The findings indicate that males, individuals of Caucasian  
8 ethnicity, those with higher incomes, and those who are not employed full-time show higher  
9 inclination to make an international trip. The likelihood of international travel tends to be higher  
10 during the summer and spring seasons. Additionally, the purpose of the trip was found to be  
11 statistically significant in the model. In order to assess the practical significance of the variables'  
12 impact on international trip decision-making, effect sizes are computed. The results show that  
13 international trip frequency (per person) rises by about 16% with a 1 standard deviation increase  
14 in the respondent's household income (i.e., \$62,000). Increasing the summer trip and spring trip  
15 indicators by 1 standard deviation also increases the frequency of international trips by 19% and  
16 14%, respectively. International trips fall by 23% when the female indicator increases by 1  
17 standard deviation, and 31% when the full-time employed indicator increases by 1 standard  
18 deviation. Religious and personal business trips are also less likely to be international.

21

22 ***Trip Distribution Model***

23 An origin-constrained gravity model was used to distribute trips among different origins and  
24 destinations. A logarithmic operator was applied to form a log-linear gravity model, and an  
25 ordinary-least-squares (OLS) model was estimated to find the number of trips distributed between  
26 each origin and destination pair. The friction factor here is a function of impedance incorporating  
27 auto and air travel times and costs (i.e., flight fare, highway toll) normalized by the value of time.  
28 The value of travel time for air travelers is assumed to be \$30 per hour and \$20 per hour for auto  
29 users. TABLE 9 shows the specifications of this log-linear model as well as the practical  
30 significance of different statistically significant variables. This model was estimated using data

1 from multiple sources indicating trip production for 334 major US airports and attractions of  
 2 country locations for 1028 international airports in countries other than the US. Due to the lack of  
 3 data about the origins and destinations of land travelers to Canada and Mexico, major airports in  
 4 most touristic cities in Canadian provinces that are accessible from the US (e.g., Ontario, Quebec,  
 5 British Columbia, Alberta, Nova Scotia) are considered as destination locations. Origins are also  
 6 assumed to be the major airport of the closest state in the US. For Mexico, all trips are aggregated  
 7 into origin and destination pair from Texas to the Sinaloa state in Mexico. The trip distribution  
 8 model indicated that trips headed to a foreign destination from an American origin fall 41% when  
 9 the travel start-to-end time increases by 7 hours, or the air ticket increases by \$210. Destinations  
 10 hosting tourist attractions increase origin-destination flow by 48% when this indicator variable  
 11 goes from 0 to 1. The population and English-speaking indicator (for the destination country) are  
 12 neither practically nor statistically significant. The modeling framework and results of this paper  
 13 can be used to craft decarbonizing policies and practices, aircraft scheduling and flight ticket  
 14 pricing, overseas investment decisions, tourism guidance and investments, and embassy  
 15 operations.

## 18 CONCLUSIONS

19 This study integrates demographic choice behavior models with destination selection based on  
 20 several trip variables and evaluates airline price changes by destination, season, and ticket type. It  
 21 uses 2019 DB1B aircraft ticket data, the 2016-17 NHTS, US outbound passenger travel aggregate  
 22 estimates of the 2019 NTTO, destination country characteristics from UN world information, and  
 23 major attraction city data for tourists in 2019 from the Euromonitor international report. The main  
 24 data source of this study, 2019 DB1B provided by BTS, revealed that the flight fare for  
 25 international travel falls as the number of passengers on the itinerary rises. Round trips made in  
 26 October to December are more expensive than those taken during the other months of the year,  
 27 while one-way trips made during April to June show high variation as compared to other times of  
 28 the year. A round trip to an English-speaking nation is less expensive than traveling to or from a  
 29 non-English-speaking country if other variables are kept constant. The international round-trip air  
 30 fares cost \$0.058 per mile flown for coach class and \$0.281 per mile flown for business class or  
 31 higher. Shifting the sample towards business or higher class increases the one-way flight fare by  
 32 125% and the round-trip fare by 151%.

33 It is important to acknowledge that the coefficients of variance model display notable  
 34 deviation from zero, indicating the presence of heteroscedasticity. The international trip choice  
 35 model reveals that the probability of taking international trips rises by 16% when household  
 36 income is increased by 1 standard deviation (i.e., \$62,000). Employment status, race, female

1 indicator, trip season, and trip purpose are other significant variables affecting Americans'  
2 international trip choice. A gravity model was used to distribute international trips among various  
3 major airports in the US and other countries. The trip distribution model indicated that travel time  
4 and cost, and tourism attractions in the destination are the statistically significant variables  
5 affecting the number of trips to an international location. This model also suggested that trips  
6 headed to a foreign destination from an American airport fall 41% when the friction factor (i.e.,  
7 travel time and normalized cost by value of time for different modes) rises by 7 hours and increases  
8 48% when all destinations shift to a tourist attraction from not being an attraction.

9 The outcome of this study can be used for targeted marketing and promotion of different  
10 tourism attractions, supporting eco-tourism initiatives and plans, planning for peak seasons of  
11 different destinations, and in general, enhancing the overall travel experience. The present study  
12 also possesses certain limitations that warrant careful consideration, thereby highlighting potential  
13 avenues for future research. As per the authors' understanding, there is a lack of publicly available  
14 data that comprehensively documents the number of international ground trips originating from  
15 cities in the United States to cities in Canada or Mexico. The dataset used in this research consisted  
16 of aggregated figures representing the number of border crossings. These figures were  
17 subsequently employed to allocate trips among various destinations, taking into account their  
18 respective tourist attractions. Furthermore, it is imperative to acknowledge that the dataset  
19 employed in this study pertains to the time frame prior to the COVID-19 pandemic. The pandemic  
20 led to unprecedented restrictions and alterations in worldwide travel patterns. Although many  
21 studies show that the demands are back to the pre-pandemic conditions, the incorporation of post-  
22 pandemic data is crucial to attain a comprehensive comprehension and adapt to the ever-changing  
23 dynamics of international travel.

## 24 **ACKNOWLEDGMENTS**

25 The authors thank the Texas Department of Transportation (TxDOT) for financially supporting  
26 this research, under research project 0-7081, "Understanding the Impact of Autonomous Vehicles  
27 on Long Distance Travel Mode and Destination Choice in Texas". The authors thank Jade (Maizy)  
28 Jeong for editorial and submission support.

## 29 **AUTHOR CONTRIBUTIONS**

30 The authors confirm contribution to the paper as follows: study conception and design:  
31 Fakhrmoosavi, F., Kockelman, Paithankar, P., Perrine, K.; data collection: Perrine, K.,  
32 Kockelman; analysis and interpretation of results: Paithankar, P., Fakhrmoosavi, F., and  
33 Kockelman; draft manuscript preparation: Paithankar, P., Fakhrmoosavi, F., Kockelman; All  
34 authors reviewed the results and approved the final version of the manuscript.
