21 22 23 24 25 26 27 28 29 30 31 32 33 34	Power companies are developing plug-in electric vehicle smart charging programs to shift charging to off-peak hours when demand is lower and to align charging with renewable energy. Anticipating public acceptance and attitudes toward smart charging programs can ensure a sustainable transportation-clean energy transition. An internet-based survey of more than 1,000 Americans ascertains opinions on supplier-managed charging (SMC) programs and the expected benefits of participating in a program. About a quarter of Americans say they would never accept SMC, but 8.8% would be willing to use an app or timer to stagger charging themselves. Up to 36.9% would cede some control to their supplier (17.6% at night only, 10.3% on grid-strained days only, and 8.9% every day to optimize the local grid). Multinomial logit models indicate that Americans with a household battery electric vehicle and wholesale-indexed energy rates are more willing to accept an SMC program. Tobit model results indicate the minimum required one-time and annual bill credits for participating in a future SMC program. These results can inform the communication and design of effective PEV charging programs to manage the new power demand by PEVs.

35 Keywords: Plug-in Electric Vehicles, Smart Charging, Willingness to Pay, Charging behavior

1 INTRODUCTION

2 The share of plug-in electric vehicles (PEVs), which include battery-electric vehicles (BEVs) and 3 plug-in hybrid electric vehicles (PHEVs), is rapidly increasing worldwide (1). Although PEVs 4 offer a new revenue source for the power industry and lower carbon emissions from transportation, 5 an increase in electricity may also create challenges in providing reliable electricity. Many power 6 grids are increasing their share of variable renewable energy (VRE) and have either limited or 7 aging transmission infrastructure not designed for a clean-energy transition (2, 3). Fortunately, 8 PEVs are considered flexible loads, meaning that their charging behavior can be influenced by 9 infrastructure provisioning and price control, thereby affecting their impacts on power grid 10 operations.

- 11 The location, supply, and type of charging infrastructure influence when and where drivers will
- 12 charge their PEVs and their consequential impact on electricity demand (4). Building public and 13 workplace charging stations can shift charging from nighttime to daytime, which may be
- advantageous in regions with an abundance of solar power. In 2021, utility-scale solar accounted
- 15 for 17.1% of California's in-state generation (5), but due to spatio-temporal imbalances between
- 16 supply and demand, the grid operator curtailed nearly 1.5 terawatt-hours (TWh) of solar power (or
- 17 5% of solar generation) (6). Aligning PEV charging demand with solar production can reduce
- 18 PEV's charging emissions and curtailment due to overgeneration, especially in temperate months
- 19 when electricity demand is relatively low (because of decreased heating and cooling demand).
- 20 Flexible PEV charging demand can also address balancing issues in the net load curve—the total
- electricity demand curve minus VRE generation—which is the amount of demand that the grid operator must supply from dispatchable sources, like natural gas peaker power plants. Filling in
- operator must supply from dispatchable sources, like natural gas peaker power plants. Filling in valleys in the net load curve by shifting PEV charging decreases ramping requirements (up or
- 24 down) and thus system costs (4, 7–9). At the distribution system level, shifting charging to valleys
- 25 in demand decreases the percentage of assets, such as transformers, that need to be augmented and
- 26 delays when improvements are needed (10).
- 27 The introduction of time-varying electricity prices, like time-of-use (TOU) or wholesale-indexed
- rates, may also motivate PEV owners to avoid charging during peak hours because of higher electricity costs (11). Studies have found that most residential customers adapt to TOU rates by
- reducing electricity consumption during peak hours (12, 13), depending on the ratio of peak price
- 31 to off-peak price (11). TOU adoption rates of 20–40% can increase PEV hosting capacity by 20%
- 32 (i.e., the number of PEVs that can charge on a distribution power network before impacts on
- 33 voltage or power quality) (10).

34 The use of time-varying electricity prices is a form of passive smart charging since the owner 35 responds to prices to alter charging behavior by either manually deciding when to plug or unplug 36 the vehicle or using an app or timer to schedule charging (7, 14). Advanced forms of smart 37 charging can also include direct (or "active") control, where the local power supplier¹ alters 38 charging behavior at smaller time steps to manage conditions in the distribution system. In this 39 study, user-managed charging (UMC) refers to an app or timer program that shifts charging, 40 controls charging speed, and/or staggers charging to avoid adding to the peak load or increasing emissions from electricity generation. Several smartphone apps are available to consumers to 41 42 smart-charge their PEV (e.g., Optiwatt and FlexCharging). Supplier-managed charging (SMC) is 43 when the charging schedule of the vehicle is coordinated and managed by the electricity supplier

¹ A power supplier is also known as a power company or electric utility.

- 1 (or contracted third-party aggregator) to meet the objectives of the supplier, so long as customer-
- 2 defined constraints, such as departure times and battery levels, are met.
- 3 The benefits of smart charging depend on PEV drivers' responses to smart charging programs and

4 their willingness to enroll in a program, be it UMC or SMC. Despite research on the financial and

5 technical requirements of smart charging, only a few studies have directly investigated consumer

6 opinions and willingness to participate in smart charging programs (15). To address this research

- 7 gap in the literature, this study addresses the following research objectives:
- Characterize opinions towards PEVs, smart charging, PEV-power grid integration, and
 preferences for smart charging (specifically within the United States context).
- Quantify the minimum financial incentives for participating in a smart charging program managed by a power supplier (i.e., SMC).

12 **PRIOR LITERATURE AND CONTRIBUTIONS**

- 13 Recently, researchers have started surveying the public to understand their perceptions of PEV
- 14 smart charging and their willingness to participate in current or future hypothetical programs,
- 15 including how they might adjust their current or expected charging behaviors. The studies either
- 16 employ charging interventions with semi-structured interviews and questionnaires or identify
- 17 respondents' preferred smart charging programs through web-based surveys. Table 1 compares
- 18 recent studies that surveyed the public about PEV smart charging².

 $^{^{2}}$ This study focuses on smart charging that controls power flow to the vehicle (also called V1G) and ignores studies on bidirectional charging (also called V2G). Readers interested in a thorough review of study methodologies and results are referred to (7).

Reference	Research Method	Sample Size	Research Questions	Main Findings
Bailey & Axsen (16)	WB-survey, LCCM	1470 new LDV buyers interested in PEVs [Canada]	- What are consumer attitudes toward SMC, including perceptions of VRE, charging inconvenience, and privacy?	 - UMC support among 50% to 67% of respondents interested in purchasing a PEV. - Concerns over privacy & loss of control with UMC. - LCCM (4 segments) vary in UMC acceptance, value of renewables, power bill savings, & charging inconvenience. - Cost-minimizing UMC program garnered 63% to 78% enrollment vs. 49% to 59% with a renewable-priority UMC. - Avg. WTP 59 CAD/year for +10 km in GMC in night-only UMC (base of 84 km).
Schmalfuß et al. (17)	Interview, Survey, SMC pilot	10 BEVs [Germany]	 What are consumer perceptions of SMC benefits, costs, and ease within daily routine? Do users trust SMC? 	 - 7/10 participants felt the perceived benefits of SMC balanced with costs of participation. - Frequency of charging increased with SMC and trust in SMC had no statistically significant change with the pilot.
Bauman et al. (<i>18</i>)	Interview, SMC pilot	30 PEVs [Canada]	 Would participants enroll in SMC if the algorithm did not consider battery levels? What compensation would lead to participation in SMC? 	 - 72% of participants would not have enrolled in SMC if the supplier curtailed charging without considering battery levels. - Over half of participants would accept SMC for less than \$10/month (and over 2/3 would accept for less than \$15/month).
Will & Schuller (19)	SEM	237 EV enthusiasts (41% PEV owners) [Germany]	- How do users perceive SC interventions in their charging behavior & what are the main factors driving the acceptance of SC programs?	 Awareness of grid operational benefits & VRE integration were important factors, while financial compensation was not significant (for early PEV adopters). SC was associated with uncertainty & anxiety. Capacity to relinquish control depended on working patterns, financial resources, & charging access.
Delmonte et al. (20)	Semi- structured interviews	60 current PEV owners & PEAs [United Kingdom]	 What are PEV users' charging behaviors? How do PEV users respond to UMC and SMC concepts? What specific aspects of UMC and SMC are appealing to PEV users & off- putting to PEV users? 	 SC engagement is conditional on lowering charging costs. 2/3 prefer UMC due to personal control, while 1/3 prefer SMC because of societal benefits. Cons of SMC are the loss of freedom and choice ("big brother") & detractors don't trust their power company.

1 TABLE 1 Synthesis of Studies Surveying the Public About PEV Smart Charging

			- How do responses differ between BEV	- UMC with TOU rates is easier to grasp but more
			& PHEV users?	difficult to use – driver must time the EV & plug-in
				before off-peak – while SMC is more difficult to grasp
				but easy to use.
Kubli (21)	WB-survey,	202 PEV drivers &	- Which consumer segments are crucial	- LCCM (3 segments) identify 53.2% are driven by
	LCCM	PEAs [Switzerland]	to consider when designing SC	charging costs & are likely earliest adopters.
			solutions?	- Incentives to switch from home to work/public
			- What compensation should operators	charging cost more than avg. charging session.
			offer to incentivize PEV drivers to adopt	- WTP for faster charging (4 hr faster) at home under
			SC?	SMC mode is 2.62 CHF.
Libertson	WB-survey,	1483 respondents, 27	- What are PEV drivers' flexibility in	- About half of drivers were upset & frustrated that
(22)	semi-	interviews with PEV	delayed charging?	PEVs were not fully charged with SMC. PHEV drivers
	structured	drivers [Sweden]		saw a delay in charging as increasing gas costs. BEV
	interview			drivers spent more time finding other public chargers.
				- Custom SMC features can instill a sense of co-control
				& trust in charging.
Wong et al.	WB-survey	784 residents in states	- What are the charging patterns of PEV	- A combination of free charging equipment, GMC, &
(23)		with ZEV mandates or	drivers now?	financial incentives increases acceptance in SC.
		high BEV adoption [33	- How can incentives influence SC	- Nearly a quarter (23%) of PEV owners & 13% of
		U.S. states $+$ DC]	among PEV drivers, potential adopters,	ICEV drivers would participate in SC without any
		_	& ICEV drivers?	incentive.
Lavieri &	WB-survey	1,000 drivers	- What are general charging preferences	- 51% of BEV drivers & 59% of PHEV drivers often or
Martins de		[Australia]	& attitudes (if PEV, then what are your	always charge to minimize downtime or maximize
Oliveira (24)			usual charging behaviors)?	convenience, vs. 21% of ICEV drivers (they prefer min.
			- What is the preferred charging option	charging costs).
			(unmanaged, UMC, SMC) and data	- 66% of PEV drivers feel comfortable ceding control
			collection (yes/no)?	vs. 32% of the public.

Abbreviations: CAD = Canadian dollar, CHF = Swiss franc, EV = electric vehicle, GMC = guaranteed minimum charge, ICEV = internal combustion engine vehicle, LCCM = latent class choice model, LDV = light-duty vehicle, PEAs = potential early adopters, PEV = plug-in electric vehicle, SC = smart charging, SEM = Structural equation modeling, SMC = supplier-managed charging, TOU = time-of-use electricity prices, UMC = user-managed charging, VRE = variable renewable energy, WB-survey = web-based survey, WTP = willingness to pay, ZEV = zero-emission vehicle.

1 Smart Charging Intervention Studies

2 Early interventions asked a small group of PEV owners (30 or fewer people) to test a smart 3 charging system at home to understand both technical feasibility and participant experience and to 4 develop recommendations for future pilot programs (17, 18). The majority of participants felt that 5 SMC's benefits balanced out with its costs (17) thanks to user-defined constraints, such as 6 minimum battery levels that must be guaranteed at departure time and readily available data on 7 their vehicle's battery levels on a smartphone app. Participants in the study by Bauman et al. (18) 8 were able to view charging sessions on a web portal and pre-set departure times and automatic 9 opt-outs from charging curtailment based on the vehicle's battery level. A survey of participants 10 after the intervention found that 72% would participate in future SMC programs if the supplier considered user-defined constraints, like the vehicle's current battery level (18). 11

12 SMC interventions were also tested outside of the home at two public parking garage charging stations in Malmö (22). Drivers charging their PEVs in the first garage were told about the 13 14 intervention, while drivers charging their vehicles in the second garage were only notified after the 15 study was completed. About half of the PEV drivers across garages were upset that their vehicles 16 were not fully charged upon their return to their vehicles. PHEV drivers felt this increased gas cost 17 because SMC did not fully charge their batteries in time for departure, while BEV drivers had to 18 spend additional time finding alternative public chargers. A subsequent web-based survey of 19 Stockholm area residents with a PEV found that 40% would accept SMC, regardless of how long 20 charging was interrupted or controlled, mostly due to perceived environmental benefits (39%), and 21 grid stability (38%). Still, if public charging stations adopted SMC, people would compensate by 22 installing home charging equipment, buying PHEVs over short-range BEVs, or buying long-range 23 BEVs instead of short-range BEVs. In other words, one's comfort level and trust in an SMC system 24 may be a function of one's financial resources.

25 Participation Incentives In Smart Charging Programs

26 Other researchers have surveyed current and potential adopters of PEVs to understand consumer 27 attitudes toward smart charging programs and identify important attributes among respondents. 28 Research across different countries has consistently identified higher support for UMC than SMC 29 because of concerns about loss of control, privacy, anxiety, and a lack of trust in their power 30 supplier (16, 19, 20, 24). Recent work has found that acceptance of SMC may now exceed that of 31 UMC, depending on PEV ownership and when people are likely to adopt a PEV. Over half of 32 current surveyed Australian BEV drivers (59.6%) would prefer SMC to UMC, compared with less 33 than a third (30.2%) of potential early PEV adopters (i.e., those who intend to buy a PEV in less 34 than a year) and 23.6% of the general driving population (i.e., those who do not intend to buy a 35 PEV in less than a year) (24). Early studies may not have observed this heterogeneity in survey 36 responses due to relatively small numbers of EVs at the time of survey dissemination and 37 participant samples that were identified as entirely potential early PEV adopters³ (16) or recruited

- 38 from PEV associations and newsletters (19).
- 39 Several studies have investigated the factors that increase participation, including financial
- 40 incentives. Delmonte et al. (20) found respondents' engagement with smart charging was
- 41 conditional on reducing charging costs. Kubli (21) identified segments in their participant pool
- 42 using a latent class choice model and found the majority of individuals (53%) placed an emphasis

³ Bailey and Axsen (16) identified these drivers through a design space exercise, where the participants designed a PEV with a purchase price that was only relatively higher than ICEVs.

- 1 on reducing charging costs over other charging attributes and would more likely alter their stated
- 2 charging behaviors if given a time-varying electricity rate. Wong et al. (23) found a 2% to 3.5%
- 3 increase in an SMC program per \$50 increase in credit, with an overall participation ceiling of
- 87% for current PEV drivers and 79% for potential early adopters of PEVs. Bauman et al. (18)
 found that half of the participants in their 2015 SMC pilot would enroll in a similar program for a
- 5 found that half of the participants in their 2015 SMC pilot would enroll in a similar program for a 6 monthly credit of \$10 (CAD), and over 67% would participate if receiving \$15 or less per month.
- 7 However, early PEV adopters may be more motivated to reduce costs than current PEV owners,
- 8 who reportedly prioritize convenience and fast charging (24). While compensation may help in
- 9 attracting PEV drivers to enroll in and stay with a smart charging program, power suppliers can
- 10 provide drivers with charging information and user-centric controls to reduce anxiety relating to
- 11 ceding control to a third party.
- 12 Lavieri and de Oliveria (24) evaluated the likelihood of participants accepting SMC if an override
- 13 feature were available in a smartphone app. Acceptance of SMC increased from 35% to 56%
- 14 among current ICEV drivers. Up to 24% of PEV owners would accept no compensation if given
- 15 information on past and current vehicle charging patterns through a web portal (18). Similarly,
- 16 Wong et al. (23) found that 26% of PEV owners and 13% of ICEV drivers would participate in an
- SMC program (for load reduction purposes) without a financial incentive. Providing a guaranteed minimum charge by departure time increased the probability of the general population
- participating in an SMC program by 14.5 percentage points. Kubli (21) found that nearly 28% of
- respondents preferred SMC to unmanaged or a form of guaranteed charge to reduce PEV charging
- 21 peaks and align with solar power, so long as suppliers did not substantially increase charging
- duration. Power suppliers may be able to call on at least 25% of PEVs to provide grid support at
- 23 no additional cost, with more drivers willing to support the grid if suppliers account for individual
- 24 PEV battery levels and charging delays.

25 Research Gaps

- 26 Despite the potential opportunities for EV smart charging to increase power grid reliability, reduce 27 charging emissions, and defer investments in storage and dispatchable generators, little work has 28 investigated the motivations for drivers to participate in a smart charging program, regardless of
- EV ownership or intent to buy a PEV in the future. Researchers have focused on current PEV
- 30 owners or those intending to purchase a PEV in the near future in their sample (16, 19–21). Thus,
- 31 these studies ignore the preferences and motivations of the anticipated late PEV adopters, who
- represent the majority of car buyers and drivers (24). Early BEV models had substantially smaller
- ranges, which might explain why Bailey and Axsen (16) found the largest group of their
- 34 participants (33%) valued increases in guaranteed range when participating in an SMC program,
- compared to cost-motivated (27%) and renewable-focused users (19%). Later work has identified
- that while charging convenience and guaranteed range are important, financial incentives may motivate more people to adopt SMC, particularly those likely to adopt PEVs in the short term. It
- is imperative to also survey individuals who may not buy a PEV in the next few years since many
- 39 auto companies will stop manufacturing ICEVs between 2030 and 2040, and governments around
- 40 the world are proposing or implementing ICEV purchase bans (1).
- 41 Studies that survey or interview PEV owners and potential adopters are few and concentrated in
- 42 Western European countries, as shown in Table 1. The public's trust in science and technology,
- 43 especially that promoted by the government, like PEVs (25), and trust in institutions and
- 44 companies, like one's power supplier or power grid operator, is regionally dependent. Thus, a
- 45 stronger understanding of charging preferences and financial incentives could guide the design of

- 1 smart charging programs and increase buy-in among current and future PEV drivers. Despite some
- 2 behavioral work on PEV smart charging, only one study has investigated attitudes and preferences
- 3 in the United States (23). Consequently, it is important to understand how Americans⁴ perceive
- 4 smart charging programs since their acceptance and willingness to alter PEV charging behavior
- 5 will influence the transition to a transportation-clean energy system. In contrast to prior work, this
- study 1) presents respondents with seven PEV charging alternatives (instead of dichotomous
 choices, like UMC versus SMC) and 2) segments results on the respondent's financial incentives
- 8 for participation in SMC by preferred charging alternative.

9 SURVEY DESIGN AND DATA PROCESSING

- 10 The data were collected via Qualtrics, a web-based survey tool, from late November to early
- 11 December 2022 across the United States. Respondents were recruited from Dynata's panel of
- 12 American respondents, ages 18 and older, ensuring no duplicate responses. The survey asked
- 13 respondents about their perceptions of EVs, smart charging benefits, SMC and UMC, and the
- 14 power grid. Respondents listed their knowledge of SMC, their preferred PEV charging style,
- 15 expected compensation with SMC, WTP to leave an automatically-enrolled PEV charging
- 16 program, current travel patterns, and demographics.
- 17 The survey employed one screening question and one within-survey data quality check to
- 18 minimize straight-lining in a section with multiple Likert scale questions. A total of 1,394 complete 19 responses were collected. After removing respondents that failed the data quality check (i.e.,
- 20 "please select slightly important") and did not meet other sanity checks, 1,050 responses remained
- 21 eligible for further analysis. Dynata recruited respondents to obtain a nearly representative sample
- 22 of the United States population according to specific demographic classes in the 2021 1-year
- 23 American Community Survey estimate (26). The unlinked classes used were gender, age,
- 24 ethnicity, educational attainment, and the four U.S. Census Bureau regions. Although additional
- variables like household residence structure type and vehicle-miles driven were not included in
- 26 quotas, the clean survey was representative of the population.
- 27 To account for built environment impacts on vehicle purchasing decisions and perceptions of EV
- smart charging benefits, the respondents' zip codes were mapped to census block groups (CBG).
- 29 Built environment attributes available at the CBG level were obtained from the Smart Location
- 30 Database (SLD), available from the U.S. EPA (27).

31 Smart Charging Concepts

- 32 In addition to the screening question, which briefly introduced the topic of smart charging,
- 33 respondents were shown Figure 1's information before answering any questions on charging
- 34 preferences.

⁴ People in the United States of America (USA) refer to themselves as Americans, which is not to be confused with the people of the Americas (the region).

Electric power companies can use prices to incentivize EV owners to charge their vehicles during low-cost hours to reduce the impacts of many EVs on the power grid. The power company can use time-of-use prices or pass down the real costs of producing electricity to the EV owner. Some EV owners use apps or timers to only charge during off-peak (or low-cost) periods. Instead of using prices to shift EV charging, power companies can directly control EV charging. Called supplier-managed charging, the goal is to reduce charging costs for the EV owner, use more renewable energy, and improve power grid reliability. 1 2 Figure 1 Survey's introductory text on smart charging programs 3 4 The introductory text provided (1) a rationale behind smart charging programs (i.e., reduce the 5 impacts of many EVs on the power grid) and (2) explained two approaches that power suppliers 6 are taking (e.g., passive smart charging through prices, adopted by users through apps/timers 7 (UMC), and active smart charging through SMC). The survey instrument had the following key 8 sections on smart charging: 9 Section A: Importance of smart charging benefits to the respondent (5-point Likert-type scale: 10 not at all important-extremely important), Prior knowledge of SMC (5-point Likert-type scale: no knowledge—extremely knowledgeable), and Interest in a smart charging program for 11 12 current/future PEV (5-point Likert-type scale⁵: not at all interested—extremely interested). 13 Section B: Preferred charging style (with nominal choices), Minimum one-time financial 14 incentive to accept SMC (truncated slider), and Minimum annual financial incentive to 15 continue participation in SMC (truncated slider). 16 Section C: Opinion on different topics related to PEVs, clean-energy transition, and values (5-17 point Likert scale: strongly agree—strongly disagree). 18 Section D: Minimum monthly fee to leave an SMC program (truncated slider). • 19 20 Sections B and D in the survey required additional text, like easy-to-understand program 21 constraints, to elicit reasonable responses from participants. Those prompts are provided in 22 subsequent sections of this paper. The survey separated questions soliciting opinions and beliefs 23 into Sections A and C to provide cognitive relief and distinguish between Section B and Section 24 D (opt-in to SMC versus opt-out of SMC). 25

26 DATA SET STATISTICS

Table 2 summarizes the respondent's demographic, household composition, residence, and vehicle variables from the complete data set. A comparison is given to U.S. census data and other appropriate data sources. The study uses some of these variables as covariates in models. The paper results are population-weighted using Table 2's sources to ensure its findings are representative of

31 Americans' preferences and values around the transportation-clean energy transition.

TABLE 2 Summary Statistics of Sample and Comparison to Nationally Representative Data Sources

⁵ Respondents with a PEV were asked about their interest in a program for their current PEV(s), while those without a PEV were asked about a future PEV. Thus, there was an additional option for those with a current PEV to capture those who already participate in a smart charging program. All results from this question grouped those already participating in programs with individuals that were "extremely interested" in participating in a smart charging program.

Solar power	5.6%	3.8%	2021 AHS		

Notes: ACS = American Community Survey, NA = not available, NHTS = U.S. National Household Travel Survey.

The American Housing Survey (AHS) excludes group quarters (e.g., nursing homes, dormitories, military housing). The respondents self-selecting non-binary/other gender were grouped with females into a non-male category in 4 regression models.

5

1 2 3

6 **SUMMARY OF RESULTS**

7 The survey asked respondents many questions related to their household structure type, their 8 vehicle use, where their primary vehicle (if any) is parked at home, future car buying decisions, 9 and barriers to buying or leasing a PEV and charging one at home. Respondents also answered 10 attitudinal questions about charging PEVs, from their participation in smart charging to how the 11 power grid might support a high number of PEVs, and how important expected PEV smart 12 charging benefits are to them. To focus on the novelty of the current paper-Americans' 13 preferences and financial incentives needed to adopt smart charging programs-the summary 14 statistics of these variables are omitted.

15 **Preferences for PEV Smart Charging**

- Respondents, regardless of whether they currently owned a PEV or were a zero-vehicle household, 16
- were asked about their preferred PEV smart charging type. They were told to assume they drive a 17
- BEV with a range of 250 miles and can charge at home at a speed providing up to 20 miles of 18
- 19 recouped range for every hour of charging (i.e., 12.5 hours from 0-100%). Respondents were
- 20 provided with the following text and choice options (Figure 2):

Given your weekly driving and (expected) charging habits, would you allow your local power company to directly control charging? The power company would use this power to mostly stagger charging schedules to avoid peaks in energy demand from BEVs.

1

Yes, I do not care what happens as long as I wake up with a full charge but do not interrupt my charging during the day.
 Yes, I would allow them to control my charger daily to optimize grid demand throughout my community.
 Yes, I would allow them to control my charger only when needed, like to prevent grid strain on days of high energy demand.
 Maybe, I would need more information to feel confident in giving up total control.
 No, but I would be willing to stagger charging myself through an app/timer.
 No, I want my vehicle to charge when plugged in and stop charging as soon as it reaches a full charge.
 I am unsure/other: _____

Figure 2 Preferred PEV smart charging option

2 A quarter of people (25.6%) say they would never allow their local power supplier to interfere in 3 charging their PEVs, but 8.8% would be willing to use an app or timer to stagger charging. Another 4 quarter (25.3%) may cede control but need more information to feel confident in giving up total 5 control. Up to 36.9% would accept SMC, but under different conditions. Most prohibit SMC 6 during the day but give up control at night, so long as the vehicle is fully charged by the morning 7 (17.6%). The next highest group would allow SMC only when needed, like during high grid strain 8 days (10.3%). And a smaller share (8.9%) would permit their power company to help optimize the 9 local grid daily.

10 Current EV owners that indicated some interest in a managed charging program (n = 124) were more likely to accept an SMC program or UMC program with an app or timer than reject managed 11 12 charging outright (Figure 3). As non-EV owners obtain PEVs and gain firsthand charging 13 experience, they may cede some control to their local power company. About two-thirds of zero-14 vehicle households (65.1%) stated they are likely to obtain a vehicle for the respondent's primary 15 use in the future, and these respondents are more unsure about accepting any charging program. 16 Designing smart charging programs that respect low trust levels may be useful in shifting 17 unmanaged and unsure respondents to UMC.

Figure 3 Preferred PEV smart charging option by household vehicle status

Note: Results are population-weighted. UMC = User-managed charging. SMC = Supplier managed charging.

5 Educational attainment can explain one's resistance to smart charging. Those preferring 6 unmanaged charging (i.e., PEV charges as soon as it is plugged in and stops charging once it is 7 full) have not earned higher education degrees. Almost a third (32.3%) of those with some 8 grade/high school education prefer unmanaged charging, versus 10.2% with a doctoral degree, 9 13.4% with a master's degree, and 12.9% with a bachelor's degree.

10 Households with a smart thermostat may also participate in a load reduction program (i.e., demand response) with their local power supplier, which raises the indoor temperature during the highest 11 12 demand peaks of the year to reduce total electricity demand from cooling. SMC programs may 13 also be designed to include a load reduction component during days of the year with the highest 14 demand for electricity. Households with a smart thermostat may be more willing than other 15 households to accept SMC on grid strain days. This study finds that a higher share of people would 16 allow SMC of their future PEV when needed, like on days with high energy demand (14.4% to the 17 average 9.1%). Regions with smart thermostat load reduction programs may see higher 18 participation rates in a PEV smart charging program because households can understand the impact 19 of demand response on cooling and compare it to their PEV⁶.

20 Many people (37.3%) were unable to recall how they pay for electricity consumption out of a list

21 of common options (e.g., fixed/flat, tiered, TOU, and wholesale-index prices). Of those that were

22 knowledgeable about their power bill, respondents with a wholesale-index power bill were more

- 23 likely to accept SMC for grid strain days and every day to optimize the local power grid's
- 24 conditions.

1 2

⁶ Behavioral research is needed to understand whether the sequential ordering of demand response programs impacts the acceptance of PEV smart charging programs with a demand response component.

1 MODEL ESTIMATION

2 A causal model was developed to assess the factors influencing the choice to participate in a 3 managed charging program. Households with a PEV in some areas of the world can choose two 4 or more charging styles (unmanaged charging, UMC with an app/timer, or SMC)⁷. Further, the 5 choices have no natural order that is uniform across individuals. Consistent with theory of 6 consumer behavior, the charging preference problem may be posed as an individual maximizing 7 its utility function. The multinomial logit (MNL) model can deal with multiple, unordered choices, 8 even with the restrictive independence of irrelevant alternatives (IIA) assumption. Even with this 9 assumption, MNL models are employed in PEV choice problems, such as where individuals charge 10 their PEV (30). The multinomial logit (MNL) model specification was preferred to nested logit models via log-likelihood ratio testing and is shown in Table 3. Covariates were chosen based on 11 12 a combination of statistical significance and behavioral importance (and results in a less precise 13 model, which is fine). The survey question on charging preference included a choice for "unsure" 14 and "other" to avoid a potential bias in results by those who are truly unsure or apathetic to the 15 listed alternatives. As a result, those respondents are not included in the n=922 sample.

16 The model included demographic variables like gender, age, educational attainment, and 17 employment status. The negative alternative specific constants (ASCs) imply a preference for 18 unmanaged charging (all else constant), with UMC more negatively perceived with respect to 19 unmanaged charging than the SMC and "maybe [SMC]" alternatives. Households with a BEV 20 overcome the negative constants for SMC-night only and SMC-daily optimization when they also 21 pay wholesale energy prices. A full-time male worker who is not middle-aged and has at least two 22 household vehicles can overcome the negative ASC for SMC-night only. If one ignores the 23 attitudinal variables, a part-time worker that pays TOU energy prices and has at least four 24 household vehicles, one of which is a BEV, can overcome the negative ASC for UMC.

25 Gender is not particularly significant in characterizing the preferred PEV charging method relative 26 to unmanaged charging. However, males are more willing to accept an SMC program to optimize local grid conditions and night-only intervention (all else being constant). Individuals ages 35 to 27 28 54 who are also unemployed (all else constant) are more willing to accept SMC-daily optimization 29 and less resistant to SMC-night-only programs relative to other choices. Individuals ages 55 to 64 30 are less willing to accept SMC-night-only programs. Perhaps these non-working adults anticipate 31 needing their PEV for nighttime travel and do not want to have their supplier interfere with 32 charging. The coefficients for other choices and age groups relative to the base of 18-34 years old 33 and unmanaged PEV charging were statistically insignificant. Individuals that completed a degree 34 higher than a GED were more willing to accept SMC-daily optimization; however, education does 35 not reduce the need for more information to make an informed decision about an SMC program. 36 Full-time and part-time workers are willing to choose UMC, but full-time workers are also willing 37 to accept SMC-night only and SMC-grid strain only. Working more hours may reduce vehicle use 38 relative to individuals working fewer hours each week and increase the opportunity for SMC, 39 particularly if the driver works from home or spends more rest time at home.

40

⁷ Please see Wong et al. (23) for a list of smart charging pilots and programs in North America; Smart Electric Power Alliance (14) for a review of 51 utilities with managed charging programs; and Hildermeier et al. (29) for a review of TOU rates and supplier-managed charging programs in Europe.

1 Households with more vehicles tend to prefer UMC, SMC-grid strain only, and "maybe" SMC 2 relative to unmanaged charging, while SMC-night only and SMC-daily optimization are not 3 statistically significant at the 10% level. Having more household vehicles can provide travel 4 security if the respondent's primary vehicle is not fully charged because of a managed charging 5 program. Of the household vehicle variables that were statistically significant at a 95% confidence interval, all are minimally invasive choices. Individuals with a household BEV are more likely to 6 7 accept UMC and SMC-daily optimization, although there is less certainty that they will accept 8 SMC-night only.

9 Households with a smart thermostat may accept SMC-grid strain over other choices since many

10 power suppliers use smart thermostats for peak load reduction a few days a year. In the future, this

11 variable might be statistically significant at a higher confidence level, especially if the variable is

12 more specific (i.e., the household participates in a load reduction or demand response program). If

13 the individual's power bill uses time-of-use prices, they are more willing to accept UMC with an

- 1 app or timer. Once the driver sets up their charging schedule with UMC, the cognitive burden is
- 2 negligible, and the individual does not have to worry about their supplier interfering in charging,
- 3 even if direct charging control is rare. Households with wholesale power prices may be more risk-
- 4 tolerant or have more demand-side flexibility (and load control) than the average household. As a
- 5 result, they are willing to accept SMC offerings like daily optimization and grid-strain events to
- 6 shift charging and help the power grid.
- 7 Household income is crossed with an attitudinal variable that signals the importance of managed
- 8 charging in reducing one's power bill. The more important saving money through smart charging
- 9 is to households making \$50,000 to \$74,999 annually (pre-tax), the less likely they are to accept
- 10 SMC for night or daily optimization relative to other choices, signaling that SMC is not viewed as
- 11 a money-saving option.
- 12 The addition of attitudinal variables significantly improves the modeling specification. Individuals
- 13 who increasingly do not want to think about how their PEV charges once plugged in prefer SMC-
- 14 night only to other options, even UMC. Perhaps respondents are willing to allow their local power
- 15 company to stagger charging at night to manage grid conditions because they do not care when or
- 16 how their vehicle charges at night, relative to UMC with non-aware charge staggering that can
- 17 create peaks of EV demand at night (31).
- 18 Individuals who increasingly agree that SMC has more risks than benefits are more likely to choose
- 19 UMC or "never" accept a managed charging program. The sign for UMC is negative relative to
- 20 unmanaged charging, even if not statistically significant. In other words, if an individual believes
- 21 that SMC has more risks than benefits, they are unlikely to accept or even consider any managed
- 22 charging program, even a user-managed program. Smart charging can reduce the curtailment of
- 23 VRE and make the grid more reliable by increasing demand-side flexibility. The more important
- the SC benefit of maximizing VRE, the more likely an individual is to accept SMC offerings or
- consider SMC (maybe). The more important the SC benefit of increasing the reliability of the power grid is to an individual, the more willing they are to accept or consider accepting smart
- 27 charging; however, SMC-daily optimization is not statistically significant in this sample.
- 28 The next set of variables are built environment indicators from the U.S. EPA's SLD (27).
- 29 Individuals residing in areas with a higher annual average concentration of fine particulate matter
- 30 are more receptive to UMC and SMC-daily optimization. As the power sector retires coal power
- 31 plants and adds VRE capacity, the transportation sector (i.e., ICEVs) will account for a higher
- 32 share of total air pollution. People residing in areas with cleaner air may be less motivated to
- 33 participate in smart charging programs to reduce air pollution from power plants; however, other 34 motivating factors may be present. Individuals living along to more becault used his because
- 34 motivating factors may be present. Individuals living close to more heavily used highways are 35 likely exposed to higher levels of air and noise pollution and may relate congestion on roads to
- 36 congestion on transmission lines. A positive and significant relationship exists between traffic
- proximity and volume with SMC-grid strain only. The Gini index is a correlation coefficient that
- 38 measures income inequality, where 0 represents complete equality and 1 represents complete 39 inequality. Individuals living in neighborhoods with higher income inequality are hesitant to
- 40 choose SMC and need more information. Individuals may hesitate to accept SMC because they
- 41 perceive a free-rider effect of PEV drivers not allowing SMC but benefiting from the actions of
- 42 other altruistic PEV drivers.
- 43 Lastly, households were asked how convenient it would be to install a charger at home if there was
- 44 not already one. Individuals that believe it is extremely inconvenient to install a charger at home

1 in their current location and are now told they have a BEV-250 vehicle with a charger at home 2 may be willing to accept SMC-daily optimization or grid strain only offerings, provided they can

3 get past the home charging barrier. Creating EV-ready building codes, subsidizing EV installation,

4 and developing inclusive utility investment programs to address disparities in residential charging

5 access are solutions that can capture these willing SMC users (32-34).

6 This model implies that BEV ownership and retail energy prices are critical factors that explain 7 smart charging preferences; however, ICEV households paying flat energy prices can still prefer 8 smart charging programs to unmanaged charging. To understand the importance of BEV ownership and wholesale-indexed electricity prices, the estimated model was used to predict the 9 10 preferred alternatives for all adults if these variables were all independently true or false. If all households had a BEV, the probability of respondents choosing UMC would increase by nearly 11 12 44 percentage points, while unmanaged charging would fall by nearly 55 percentage points. If all households paid wholesale energy prices, the predicted probability of choosing unmanaged 13 charging would fall by 48 percentage points. Figure 4 shows the change in the probability of the 14 15 preferred PEV smart charging choice if all households owned or leased a BEV, relative to having 16 no BEVs. Similarly, the figure shows the scenario where all households paid wholesale-indexed

17 energy rates relative to households paying all other retail rate types.

19Figure 4 Predicted shifts in preferred alternatives with shifts in BEV ownership and20wholesale-index energy price indicator variables (0% to 100%)

21

18

22 Financial Incentives for Supplier-Managed PEV Smart Charging

After individuals selected their preferred PEV charging program, they were told to assume they participated in an SMC program. Again, they had the same information (e.g., they drive a BEV with a range of 250 miles and can charge at home at a speed providing up to 20 miles of recouped range for every hour of charging). Respondents selected the preferred one-time bill credit for participating in an SMC program using a slider scale, from \$0 to \$200, with the option to mark "more than \$200." Respondents were provided with the details shown in Figure 5. 1

Your local power company gives you a one-time bill credit (\$) if you participate in an EV smart charging program. The power company studies your EV charging patterns for one month and creates a custom charging schedule for you. This allows the power company to charge EVs at a lower cost without impacting your travel needs. Details:

- For overnight charging, you allow the power company to charge your EV whenever, so long as you receive a full charge by the morning. Your vehicle is charged sometime between the hours of 10 PM and 6 AM.
- For daytime charging, the power company can interrupt charging during extreme events (no more than 5 times a year). Otherwise, your charging is not affected.
- Must stay enrolled in the program for at least 1 year to receive the one-time credit.

What is the smallest one-time bill credit (\$) you would accept to allow your local power company to modify your EV charging when plugged in?

Figure 5 Survey prompt on minimum financial incentives for participating in PEV smart charging programs

The range in one-time bill credit was adjusted down from the potential per-vehicle value of smart charging found in the literature, which primarily centers on the California market, where electricity prices are higher than the national average (7). While all respondents selected their preferred onetime credit to accept SMC, not everyone is willing to accept SMC, let alone UMC. Due to the declining marginal value of managed charging with increasing PEV penetration (*35*), it may be advantageous for power suppliers to study the value of smart charging locally and use price

10 discrimination to reward those offering the highest value.

11 People who previously said they would be willing to cede control to their power company for the 12 benefit of the community (SMC-daily optimization) and during grid-strained days (SMC-grid 13 strain only) are willing to accept a lesser one-time credit—an average of \$96.33 and \$99.57, 14 respectively (Figure 6). Those that would only permit control during grid strain (SMC-grid strain 15 only) ask for an average of \$100.38. The three groups that previously preferred SMC do not ask for high one-time bill credits-9.3% to 20.0% of these respondents selected the checkbox for 16 17 "more than \$200," versus 23.9% to 38.9% of respondents choosing the non-SMC choices. 18 Although SMC may entail higher administrative and technical costs than UMC, the value to 19 utilities is higher, and the supplier may have a greater return on investment. Instead of paying 20 UMC users an extra \$26 to \$30 per vehicle to participate in SMC, the power company may decide

21 to shift more drivers from the unmanaged category to UMC.

Respondents answered how much money they would require each year for ongoing participation on top of the one-time incentive. The slider question was scaled down from \$0 to \$20, with an option to mark more than \$20. Those who allow SMC-daily optimization require more annual

option to mark more than \$20. Those who allow SMC-daily optimization require more annual compensation than those allowing SMC-grid strain only, which reflects the higher chance of

26 intervention by the power company and possible inconvenience (\$13.50 to \$12.89). A higher share

27 of individuals requires a yearly credit above the slider scale, which was set at \$20 for this survey.

Figure 6 Preferred minimum one-time and annual bill credit for SMC participation (segmented by PEV charging preferences)

Note: Boxplot excludes those selecting the checkbox for "more than \$200" or "more than \$20." The percent of rightcensored data by preferred charging style and bill-credit is provided to the right of each boxplot. Boxplot data shows population-weighted survey data which explains the whiskers that exceed the limits.

8 A Tobit model, also known as a censored regression model, was developed to estimate the 9 preferred one-time SMC and annual participation credit, since the survey used a slider scale with 10 a checkbox for values exceeding the maximum sliding scale (\$200 and \$20 for one-time and annual 11 credits, respectively. Tobit models assume normality and homoscedasticity in the distribution of residuals, and when heteroscedasticity is present, the results are biased (36, 37). Residual plots 12 13 with censored regression models indicated the data did not display homoscedasticity. Thus, Messner et al.'s heteroscedastic censored regression model with a logistic distribution was used 14 15 (38). The left limit for the censored dependent variable was \$0 and the right limit was \$200 and 16 \$20, respectively.

17
$$y_{i} = \begin{cases} y_{i}^{*}, y_{L} < y_{i}^{*} < y_{U}, \\ y_{L}, y_{i}^{*} \leq y_{L}, \\ y_{U}, y_{i}^{*} \geq y_{U}, \end{cases}$$
(1)

18 where y_L and y_U are the respective censoring limits (lower and upper) and y_i^* is the latent variable.

19 A subset of explanatory variables was first included when estimating the Tobit model. In 20 subsequent steps, the covariates with the lowest statistical significance were removed using 21 likelihood ratio tests, except for gender and race, as such covariates may offer statistical 22 significance in future studies. In addition to statistical significance, practical significance values 23 are shown to reflect the importance of covariates on the dependent variable (i.e., payments for 24 SMC). Practical significance measures the change in payments due to a one-standard deviation change in each covariate. Covariates with standardized coefficients greater than 0.5 are considered 25 26 "practically significant." Table 4 presents results on the one-time payments and annual payments.

- Females that do not identify as Asian/Pacific Islander/Asian American, are between 18 and 24 years old, do not trust their power company to always guarantee a fully-charged EV, and perceive
- 3 smart charging's benefit of increasing grid reliability as important (all other predictors constant),
- 4 are estimated to have higher minimum one-time payments to allow their local power company to
- 5 modify EV charging (i.e., SMC), while Asian American males who agree that EV owners should
- 6 pay higher fees on power bills and are interested in long-range BEVs exclusively place a lower
- 7 value on one-time bill payments to permit SMC. Perhaps those willing to pay additional monthly
- 8 power fees that go to upgrade grid infrastructure and those preferring long-range BEVs are able to
- 9 perceive their impact on the power grid and need less financial incentive to permit their local power
- 10 company to modify their charging behavior.
- 11 **Table 4**: Minimum one-time and annual bill credit for SMC participation.

Note: All Std. Coef., which are greater than 0.5, are in bold, and indicate practically significant predictors. Results are
 population weighted/sample corrected. VMD = Vehicle-miles driven.

14 Females that do not identify as White Hispanic/Latino, agree that smart charging is a net good for

society, and perceive smart charging's benefit of increasing grid reliability as important (all other

16 predictors constant), are estimated to have higher minimum annual payments to allow their local

power company to modify EV charging (i.e., SMC), while young adults between 18 and 24 with

18 a maximum household pre-tax income of \$30,000 and agree the power grid can support the

19 government's EV adoption goals place a lower value on annual bill payments to permit SMC.

- 1 Perhaps full-time working young adults making at most \$15/hour who believe the power grid can
- 2 support the government's ambitious EV adoption goals do not value charging flexibility as high
- 3 as others or are not as financially driven as others in continuing to participate in an SMC program.

4 CONCLUSION AND POLICY IMPLICATIONS

5 This study used multinomial logit and Tobit models to understand the impact of demographics,

6 travel characteristics, built-environment factors, and transportation-clean energy nexus opinions

7 and values on Americans' preferred PEV charging program and desired payment for participating

- 8 in an SMC program.
- 9 Results suggest that households paying time-varying power bills, like TOU, prefer UMC with an
- 10 app or timer relative to other options. Households with wholesale-indexed rates may be more risk-11 tolerant and prefer SMC to optimize local grid conditions daily or only during grid strain days.
- Households with a BEV have experience charging their vehicle and may have a more informed
- 13 stated preference regarding an SMC program, even though they are not widely available, unlike
- 14 UMC programs. These households are willing to accept UMC and SMC for grid optimization and
- 15 night-time interventions, but there was no statistically significant covariate for grid strain days.
- 16 Individuals that believe it is extremely inconvenient to install a charger at home and are told to
- 17 imagine they have a 250-mile-range BEV with a charger at home may be willing to accept SMC
- 18 for daily optimization or grid strain days, but only if they can get past the home charging barrier.
- 19 Cities need to ensure that buildings have the electrical wiring to support EV adoption, while power
- 20 suppliers need to lower capital costs and regulatory barriers (e.g., permits) to support the retrofit
- 21 of existing residences.
- 22 Attitudinal variables greatly improved model fit but are hard to measure in the real world to predict
- the adoption of managed charging programs. The results indicate that individuals who do not want to think about how an EV charges are more willing to accept night-only SMC, which can help avoid TOU-created electricity demand spikes from PEVs. The more important the benefit of maximizing renewables or increasing power grid reliability, the more likely an individual is to
- accept SMC offerings or consider SMC. Power companies could survey their customers annually
- or when sending out monthly bills to receive this attitudinal data. This information could allow
- 29 them to tailor incentives to the local market to increase smart charging adoption while ensuring
- 30 the cost of incentives is less than the added value.
- 31 Individuals that prefer SMC offerings may be more altruistic than those accepting UMC or those 32 not willing to modify their charging behaviors, and they would expect less money for their 33 participation in a future SMC program. Perhaps the lower payment is because they were already 34 willing to participate in SMC and would not require additional compensation for less flexibility. 35 Since individuals preferring UMC demand more compensation to participate in an SMC program, 36 power companies could seek higher enrollment in UMC through lower off-peak prices rather than 37 paying consumers to adopt SMC. Tobit models found that Asian American males who agree that 38 EV owners should pay higher fees on power bills and are interested in long-range BEVs tend to 39 accept smaller one-time bill credits to permit SMC. Perhaps individuals that perceive impacts of 40 EVs on the power grid need less financial incentive to permit their local power company to modify 41 future charging behavior. Females that do not identify as White Hispanic/Latino, agree that smart 42 charging is a net good for society, and perceive smart charging's benefit of increasing grid reliability as important (all other predictors constant), are estimated to have higher minimum 43
- 44 annual payments to allow their local power company to modify EV charging.

- 1 Our survey design centered on consumer flexibility in smart charging programs. When respondents
- 2 were asked whether they would allow their local power supplier to directly control charging, the
- 3 choices were not binary (i.e., yes or no). This choice structure is important since many individuals
- 4 have two or more charging options today. Respondents were told that adjustments to PEV charging
- 5 would not interfere with their travel needs and would be made based on historical data. Providing 6 respondents with several alternatives in response to this question, namely never managed,
- respondents with several alternatives in response to this question, namely never managed,
 unmanaged charging, UMC, and three SMC alternatives that were not rigid contracts (e.g., must
- 8 be plugged in for 8 hours overnight at least three days a week), revealed nuanced preferences that
- 9 other studies missed. The survey data on preferred one-time and yearly credits for SMC
- 10 participation may indicate minimum incentive levels if power companies ignore individual
- 11 preferences and uniformly alter PEV charging (i.e., contract-based PEV smart charging). Future
- surveys should continue to understand consumer needs and preferences through this approach to provide power companies with more flexible and low-cost smart charging options.
